

What is the primary beam  
response of an interferometer  
with unequal elements?

Richard Strom

ASTRON & University of Amsterdam

# Rationale: comments such as –

☞ I want an in-beam reference source...

Hmm...

The largest element in the array has a FWHM beam of 9' arc...

I guess I should look for a source within 4.5' arc of my target...

☞ Anything wrong with this? Uh, yes...

# We all know the FWHM of a radio telescope:

- For a 25 m dish,  $\sim 30'$  arc at 18 cm;  
 $\sim 10'$  arc at 6 cm;
- For a 100 m dish,  $\sim 7.5'$  arc at 18 cm;  
 $\sim 2.5'$  arc at 6 cm;
- ...etc.
- An interferometer then? For the VLBA it's simple: all elements are 25 m.

# What's the EVN situation?

| Diameter            | Station(s)        |
|---------------------|-------------------|
| 200 m (illuminated) | Ar                |
| 100 m               | Eb                |
| (14 x 25 m)='90 m'  | Wb                |
| 76 m                | Jb1               |
| 70 m                | Rb70              |
| 32 m                | Cm,Mc,Nt,Tr,Rb34  |
| 25 m/85 ft          | Hh,Jb2,On85,Ur,Sh |
| 20 m                | On60, Wz          |

# What happens with unequal elements, as in the EVN?

- Might guess that the beam will be some average of the two elements...
- Everyone should know that for elements with area  $A_1$ ,  $A_2$  and  $T_{\text{sys}}$  of  $T_1$ ,  $T_2$ , the interferometer area and  $T_{\text{sys}}$  will be:

$$A_{12} = (A_1 A_2)^{1/2} \quad \& \quad T_{12} = (T_1 T_2)^{1/2}$$

# Consider the beamshape of a single dish

- The antenna response,  $A$ , is the FT of the autocorrelation of the aperture illumination,  $v$ :  $v * v \Rightarrow A$

( $\Rightarrow \equiv$  FT;  $*$   $\equiv$  correlation/convolution)

- Hence,  $v \Rightarrow V$  &  $a \Rightarrow A$

- Then, by the convolution theorem,

$$v * v \Rightarrow V \times V = A$$

( $V$  is the antenna voltage pattern.)

# What is the combined beamshape of an interferometer?

- The antenna response,  $A_{12}$ , is the FT of the cross-correlation of the 2 aperture illuminations:  $v_1 * v_2 \Rightarrow A_{12}$
- Then, by the convolution theorem,  
$$v_1 * v_2 \Rightarrow V_1 \times V_2 = A_{12}$$
- For  $v_1 \gg v_2$ ,  $V_2 \sim \text{const}$ , so  $A_{12} \sim V_1$
- This results in a broader main beam lobe

# EVN element and interferometer beam properties at 18 cm

| $St_1 * St_2$ | $\theta_1$ | $\theta_2$ | $\theta_{12}$ | $\Omega_{12} / \Omega_1$ |
|---------------|------------|------------|---------------|--------------------------|
| Ar*Eb         | 2.9'       | 7.4'       | 3.8'          | 1.74                     |
| Ar*Jb1        | 2.9'       | 10'        | 3.9'          | 1.84                     |
| Ar*Sh         | 2.9'       | 30'        | 4.1'          | 1.98                     |
| Eb*Jb1        | 7.4'       | 10'        | 8.4'          | 1.3                      |
| Eb*Sh         | 7.4'       | 30'        | 10.2'         | 1.9                      |
| Jb1*Sh        | 10'        | 30'        | 13.4'         | 1.8                      |
| Mc*Sh         | 23'        | 30'        | 26.0'         | 1.25                     |

# Interesting (?), but so what?

- ☞ If your only concern is what goes on within  $<1''$  arc, you're not affected.
- ☞ If you want an in-beam reference source, then you might be interested.
- ☞ For wide-field mapping, this should certainly interest you!
- ☞ (And in any event, it's fundamental.)

# Postlude: what is the effect?

- ☞ Sources off axis will be attenuated in the sky plane (in the  $u, v$ -plane, the visibility will be convolved by the FT of the interferometer primary beam).
- ☞ This can be different for different baselines.
- ☞ Will affect map, but also self-cal.
